Disparities in patients with tic disorders

Presented By:
Natalia Szejko¹, MD, PhD, ScD
Christelle Nilles², MD

1. Department of Clinical Neurosciences, University of Calgary, Canada
2. Department of Neurology, Université Paris Cité, Paris, France
OVERVIEW OF THE TALK

1. Overview of cultural disparities in GTS
2. Overview of previous studies reporting about diverse ethinical groups
3. Racial and non-racial disparities analysis in All of Us Cohort
4. Sex differences in tic disorders
Cultural/ethnic disparities

• an overrepresentation of GTS literature from European and North American perspectives
• the heterogenous nature of GTS
• the influence of race, culture and environmental factors on symptom expression
• GTS is seen less frequently in some cultures?
• Not diagnosed?
• Other diagnostic criteria (China)
• Lack of awareness?
• In all cultures the tic phenomenology is similar (biological underpinnings)
• There may be some variations in the occurrence of co-morbidities

*Characteristics selected for inclusion in the national survey questionnaire. 
†Unweighted sample sizes. 
§Weighted prevalence estimates. 
¶Federal poverty level.
• The clinical characteristics of TS were similar to that found elsewhere.

• The perceived impact of TS was different.

• Many subjects denied that their TS caused impairment or distress, even when objective evidence of impairment was available.
Culture and disease perception

Culture and the understanding of advanced heart failure: A mixed-methods systematic review

2023 TIC-CON | touretteconference.org
Two diseases have been spectacularly, and similarly, encumbered by the trappings of metaphor: tuberculosis and cancer.

In Stendhal's *Armance* (1827), the hero's mother refuses to say 'tuberculosis,' for fear that pronouncing the word will hasten the course of her son's malady.
• No studies from multicultural/multiethnic countries, such as USA and Canada
• Growing literature from China, Taiwan and Japan

Current Status, Diagnosis, and Treatment Recommendation for Tic Disorders in China

Roberston (2008) The prevalence and epidemiology of Gilles de la Tourette syndrome: Part 2: Tentative explanations for differing prevalence figures in GTS, including the possible effects of psychopathology, aetiology, cultural differences, and differing phenotypes
Voices from the Community:

“My name is Carter Jackson, and I was diagnosed with #TouretteSyndrome around 12 years old. I’m currently 21 and a working, part-time student. As a black, transgender man with #Tourette, it has been difficult at times to navigate

“My son was diagnosed with #Tourette in February of last year. We didn’t know what it was or what to do. Teachers and peers taunted him, and he didn’t understand why he was different suddenly. But at 9, he kept pushing forward and continued to play football and basketball. Each day he is learning to live with Tourette and I am honored to be his mom.

In the beginning, Jaiden was nervous but he did educate his coaches which wasn’t too hard because one is his dad. But for flag f... See more

“My daughter, Jamariah, was diagnosed with #TouretteSyndrome last year! It’s been a struggle and we’re starting to finally adjust. We’ve had to learn how to overcome people staring in public places, and kids saying things or laughing at her because of her jerking and grunting. I’ve explained to many kids in the classroom setting and in our hometown about her tics. I’ve shown videos so others could understand what tics were and why they occur.
**Genetic studies**

- Most (GWAS) have been carried out in populations of European descent
- Few results from other populations showed population-specific results

*a* Position according to GRCh 37.

*b* Reference/mutation allele.
Racial and non-racial disparities in tic disorders in the United States: analysis of All of Us Study

OBJECTIVES

• determine whether the prevalence of tic disorders varies depending on race, ethnicity and gender

• Cross-sectional analysis of All of Us research program

• National Institutes of Health database that is designed to provide health and genetic data on over 1 million Americans, focusing on groups that have generally been underrepresented in research
Racial and non-racial disparities in tic disorders in the United States: analysis of All of Us Study

METHODS

- Tic disorders cases were identified in Electronic Health Record data using ICD-9-CM, ICD-10-CM and SNOMED codes
- We calculated the prevalence of diverse tic disorders among participants across self-identified racial and ethnic groups
Results

• **369,297** All of Us participants with available data (average age 56 years, SD 19; 59 % female)

• **3134** patients with diverse tic disorders with an average age of 54 years (SD 12) and female predominance (n=1685, 54%)

• No difference in tic prevalence in males and females (0.8 vs 0.7%)

• When comparing tic prevalence among diverse racial groups, the highest prevalence was among **Whites** (n=2060, 1%), following by Asians (n=94, 0.7%) and Blacks and African Americans (n=461, 0.6%)

• Similarly, tic prevalence was statistically significantly higher in ethinical group of not Hispanic or Latino (n=2604, 0.9%) vs 0.4% in Hispanic or Latino group (n=276)
Conclusions

- In the All of Us study, the prevalence of tic disorders among US adults was 0.8%.
- The highest prevalence was detected in *Whites* and the ethnical group of *not Hispanic or Latino*. 
1. Overview of cultural disparities in GTS
2. Overview of previous studies reporting about diverse ethnical groups
3. Racial and non-racial disparities analysis in All of Us Cohort
4. Sex differences in tic disorders
• Like in other neurodevelopmental disorders (ASD, ADHD), there is a male predominance in Tourette syndrome (TS).

• Attenuation with age:
  - Childhood: Sex ratio 3-4 males : 1 female.¹
  - Adulthood: Sex ratio 2 males : 1 female.²,³

Are there sex-specific phenotypes and prognoses for TS?

¹Knight et al, 2012; ²Schlander et al., 2011; ³Yang et al., 2016.
Exploration of sex differences in tic disorders in childhood
Influence of sex on tic severity and psychiatric comorbidity profile in patients with pediatric tic disorder

JOSEPH GIRGIS¹ | DAVIDE MARTINO² | TAMARA PRINGSHEIM²,³

- Cross-sectional study in 270 children and adolescents (aged 5-17y, mean 10y 6mo), 212 males and 58 females

- **Objective:** to examine differences in tic severity and comorbidity profiles between the sexes

<table>
<thead>
<tr>

</tbody>
</table>
Increased symptom severity with increased age was more pronounced in females for all the measurements except for tic-related impairments.

Motor tic severity ($p=0.025$), tic-related impairments ($p=0.051$), and global severity ($p=0.045$) were higher in females at all ages.

Vocal tics were more severe in males at a younger age ($p=0.121$) but were more severe in females at an older age ($p=0.077$).

Girgis et al, 2021
N=203 children and adolescents with primary tic disorders.
- 76.4% males.
- Mean age: 10.7y.
In comparison with young males, young females had:

1) More simple tics: nose movements (OR=2.87, p=0.003), shoulder shrugs (OR=2.52, p=0.010), simple leg/foot/toe movements (OR=2.11, p=0.040), sniffing tics (OR=2.21, p=0.027) and grunting tics (OR=4.10, p=0.016)

2) Higher frequency (p=0.032) and intensity (p=0.006) of motor tics and greater tic-related impairment (p=0.045).

HYPOTHESES

• Differences in tic awareness and self-report of tics?
• Increased levels of stress and depression in females?
• Different phenotype and natural history of tics based on sex?
What about sex differences in adults with tics?
A GROWING INTEREST IN SEX DIFFERENCES IN TIC DISORDERS

Sex differences in patients with Tourette syndrome

José Fidel Baizabal-Carvallo\(^1,2\) and Joseph Jankovic\(^1\)

\(^1\)Parkinson’s Disease Center and Movement Disorders Clinic, Department of Neurology, Baylor College of Medicine, Houston, Texas, USA and \(^2\)Department of Sciences and Engineering, University of Guanajuato, Guanajuato, México

- **N=201 individuals** (age 4-65 years) with tic disorders
- Males < 18 years had a greater complexity and severity of tics than females (p=0.049). These differences were not present in subjects > 18yr.
- Only females had increased tic complexity and severity in adulthood compared to childhood.

In the longitudinal European Multicenter Tics in Children Study\(^1\) (16 different centres, n=709 children and adolescents with TS/persistent tic disorders): greater tic severity in boys, but higher tic severity in girls with age.

\(^1\)the EMTICS collaborative group et al, 2021
• N=164 adults with tic disorders; mean age: 32.9y in French participants, 31.7y in Canadian participants. 88% had TS.
• Sex ratio 1.9 males: 1 female.

In the Canadian subgroup
• Women had more simple hand tics than men (OR=2.96, p=0.03)
• Women had a greater complexity of motor tics (p=0.048), a greater motor tic score (p=0.03), and a greater tic-related impairment (p=0.003) than men.
In our study, sex ratio was 1.9 males:1 female.

→ Females have less resolution of symptoms with age?
→ Women seek health-care more often in adulthood due to higher tic-related impairment?
→ Underdiagnosis of TS in girls in childhood?

Cross-sectional study in 185 females and 275 males with tic disorders, aged 18-79 years

- Women experienced greater tic-related interference in their social lives than men.
- 1/3 women first received treatment >18 years.

Study in 75 adults with TS from a university-based clinic

- Women had higher YGTSS motor tic severity scores than men (p=0.036) and greater TS-related impairment.
- Women were more likely than males to show expansion of the number of body regions affected by tics and to have a tic worsening as opposed to tic improvement in adulthood.

1Lewin et al, 2012; 2Lichter et al, 2015
• In the Canadian subgroup, women had more anxiety disorders than men (OR=3.18, p=0.01).

• In the French subgroup, women had more OCD than men (OR=4.84, p=0.02).

• Females with TS are more likely than males to have depression and anxiety.¹

• Tic severity correlates with comorbid depression in children and adolescents ² and in adults ³ and with comorbid anxiety. ⁴

→ The high prevalence of mood and anxiety disorders in women with TS may play a role in the severity of their tics.

Substrates underlying sex differences in TS
Sex and gender in neurodevelopmental conditions

Explores the sex and gender-related factors (biological, behavioural) that influence neurodevelopmental conditions.
Brain imaging studies have suggested that males with TS might have more widespread brain alterations than females with TS compared with typically developing peers.¹

- Altered cortical and callosal thickness and basal ganglia volume in childhood.²,³

- ↓ cortical thickness in prefrontal, orbitofrontal and parietal regions.⁴

¹Bölte et al, 2023; ²Garris et al, 2021; ³Pinares-Garcia et al, 2018; ⁴Fahim et al, 2010
Hormones (PCOS)\(^1\)

A twin study in Sweden (n=17,220 twins) found a heritability of 0.39 in boys vs 0.26 in girls.\(^2\)

Genetics

Later studies failed to support greater heritability in males.\(^3\)

Social experiences

\(^1\)Dubey et al, 2021;  \(^2\)Anckarsäter et al, 2011;  \(^3\)Qi et al, 2017
• Overall, although findings on sex differences before age 18 varied, there is accumulating evidence that females may have slightly greater tic severity and tic-related impairment with age.

• Sex seems to contribute to the variability in TS via genetics, endocrinological factors, brain structure, behaviours, comorbidities…

• Future research: exploring the female experience of tic disorders in childhood and adulthood; considering sex but also gender in studies; examination of the association between tic severity and tic-related impairment in women versus men; imaging studies.
Thank you for your attention!
